

Meta-Analysis to Meta-Cognition

Following the Bayesian Highway in Cardiology

Jay Brophy MD PhD

McGill University — Departments of Medicine, Epidemiology & Biostatistics

2025-09-11

Overview

- Why Bayesian thinking matters in modern evidence synthesis
 - Revisiting meta-analysis through a Bayesian lens
 - From inference to *meta-cognition*
 - Two current cardiovascular examples
 - Colchicine post-ACS
 - Early AVR in asymptomatic severe AS

What is Meta-Analysis (MA)?

- Statistical method combines multiple studies to estimate a common effect, θ and between-study variation, τ
- Very common (29,824 publications with MA in title so far in 2025)
- Common MA methods (frequentist) have limitations / assumptions
 - θ is a single fixed (but unknown) constant** and only the data are random, consequentially
 - 95% CI is a property of the procedure, not θ
 - IOW If repeated the studies many times, 95% of such intervals would cover θ
 - Ignores prior ancillary θ knowledge
 - Arbitrary decision thresholds ($p < 0.05$)
 - Can't make probability statements about θ or answer clinical questions like: "How likely is the effect big enough to matter in my setting?"

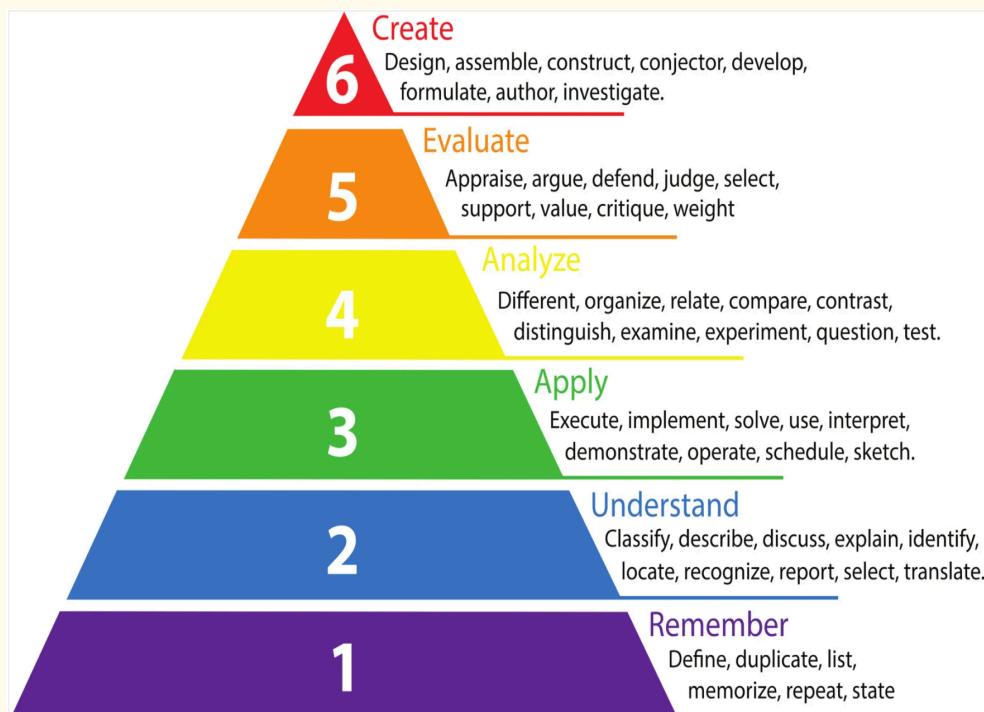

meta — prefix of Greek origin meaning “after, higher, beyond”

Bayesian thinking in cardiology

What is Meta-Cognition?

- **Meta-cognition = thinking about thinking**
- Traditional inference asks: "Is there an effect?"
- Meta-cognition extends with purposeful reflection and situational awareness:
 - "Is the effect large enough to matter?"
 - "What should I do given this evidence?"
- For example: RR = 0.85 with 95% CrI [0.60, 1.08], p = 0.28
 - Recognize p > 0.05 doesn't imply clinical irrelevance
 - Should you act, wait, or gather more evidence?
 - What is the probability that the benefit exceeds my clinically important difference (CID) threshold?

Taxonomy of Learning

Overview Of Bloom's Taxonomy

- Meta-cognition - Reflects Bloom's top tiers: **Evaluate** and **Create**
- **Evidence → Insight → Action**
- Enables clinicians to:
 - Question assumptions
 - Integrate uncertainty
 - Move beyond binary decisions (significant vs not)
 - Tailor decisions (shared, informed) to context

Meta-Cognition and Bayesian Meta-Analysis

Meta-cognition: the destination — clinical wisdom beyond the numbers, deeper understanding, communication and wiser decisions

Bayesian meta-analysis: the statistical engine (the GPS) - navigating uncertainty with purpose - to get to our destination

Why Bayesian?

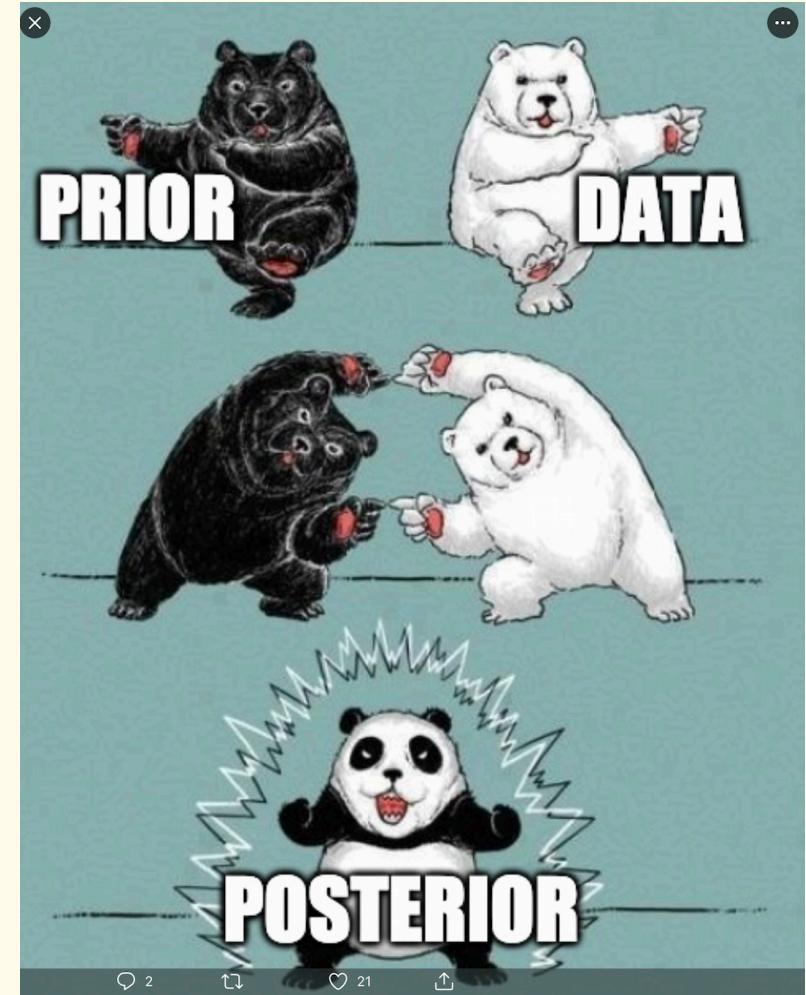

- Bayesian meta-analysis:
 - Combines data *and* prior information
 - Offers full probability distributions for effect sizes
 - Naturally accommodates uncertainty, decision-making, prediction

["Bayesian inference is what you do when you believe you should condition on what you know." — Andrew Gelman]{large-text red-text}

Bayesian Key Concept

Posterior \propto Likelihood \times Prior

- Prior: What you believe **before** the new evidence
- Likelihood: What the new data say
- Posterior: What you believe **after** combining both

Prior Knowledge: A Strength or Bias?

- Strength: Informs inference, enables cumulative learning
- Criticism: “Subjective”
- Response:
 - All models involve assumptions
 - Assumptions can be tested
 - Bayesianism just makes assumptions (priors) explicit

Frequentist vs Bayesian Meta-analysis

Feature	Frequentist	Bayesian
Point estimate	Yes	Yes
Confidence/Credible Interval	CI (coverage probability)	Crl (posterior probability)
Interpretations	Long-run frequency: 95% of intervals cover true effect	95% chance the true effect lies within the interval
Probability Statements	Not valid for individual studies or patients	Directly answer "how likely" questions
Shrinkage	No	Yes (esp. in hierarchical models)
Predictive intervals	Limited (available in mixed models)	Yes (posterior predictive distribution)
Parameter interpretation	Fixed (unknown constant)	Random variable with probability
Prior inclusion	No	Yes
Tailored Inference	No	Yes (e.g., $P(RR < 0.9)$, threshold-specific)

Predictive Thinking: The Next Study

Pooled average = typical effect across included studies

Predictive interval = likely next-study range (includes between-study heterogeneity, τ^2)

Frequentist

- Parameters are **fixed**, data are **random** -> probability statements about the true effect are **not defined**
- Prediction interval = future observation given fixed parameters
- Interpretation:
> "There is a 95% chance that the next observation falls within this interval, *if the parameters are correct*"

Bayesian

- Parameters are **random variables** with distributions, data is **fixed** → probability statements *about the effect* are **valid**
- Posterior predictive distribution integrates over parameter uncertainty
- Interpretation:
> "There is a 95% probability that the next outcome lies in this range, *given our data and prior*."

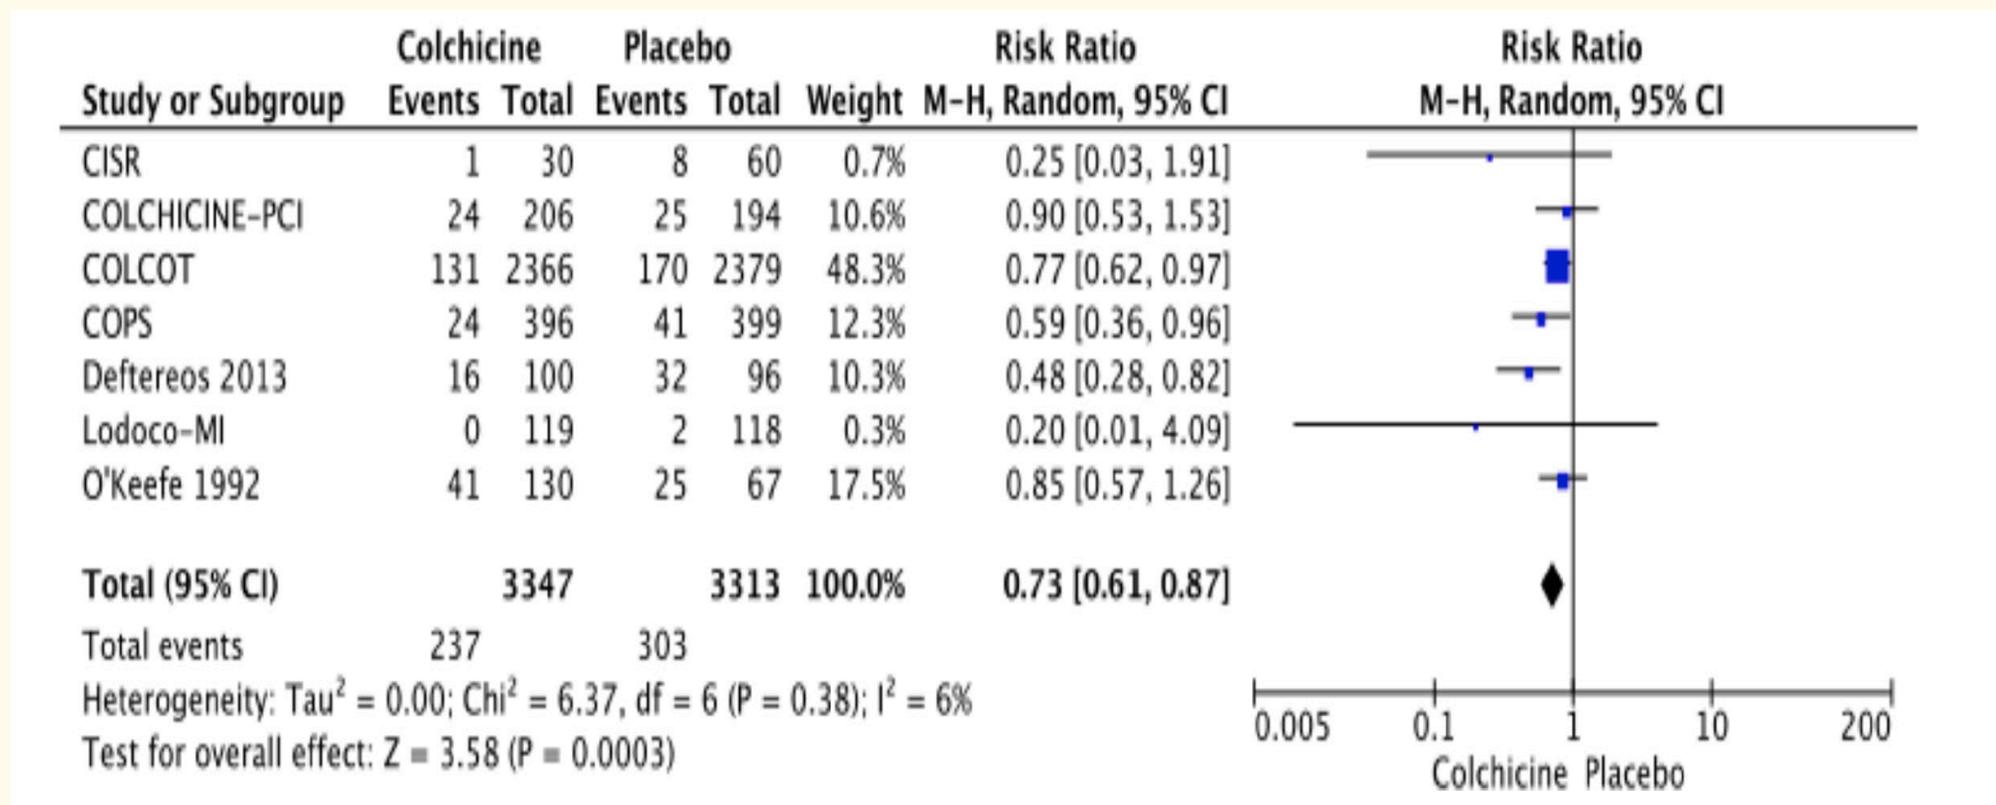

Clinically Important Difference (CID)

CID probabilities only available with Bayesian approach

- Define a CID based on clinical context:
 - e.g., ARR $\geq 1.5\%$ over 3 years (RR ≤ 0.85 if baseline risk = 10%)
- Report:
 - $P(RR < 1.0)$ (any benefit)
 - $P(RR \leq \text{CID})$ (Bayesian-only)
 - Predictive interval for a new, comparable study
- Decision:
 - treat when $P(RR \leq \text{CID})$ is high *and* the predictive interval lies mostly on the favorable side.

Colchicine in ACS

Colchicine's role in post-ACS care - a 2022 frequentist meta-analysis

Conclusion: “Colchicine significantly reduced the risk of MACE in CAD patients”
 Is the colchicine / ACS story over, or is further research justified or even ethical?

Not so fast...

- No prediction interval (PI) for next study provided
- Frequentist PI (0.60 - 0.90) assumes study parameters & statistical model are known without uncertainty -> overconfident conclusions
- Bayesian PI for next study accounts for parameter variability -> CI 0.35 - 1.29
- Providing more realistic heterogeneity estimate and justification for future studies

CLEAR Trial: Colchicine in ACS

Some investigators obviously didn't believe the colchicine story was over

CLEAR Trial (2025) published in NEJM 2025

- 7062 patients randomized at 104 centers in 14 countries
- Primary outcome: CV death, MI, stroke, or urgent revascularization
- Results: RR = 0.99 (95% CI 0.85–1.16, p=0.93)

Conclusion: "Treatment with colchicine, when started soon after MI and continued for a median of 3 years, did not reduce the incidence of the composite primary outcome."

Colchicine Meta-Analyses in 2025

CLEAR did not discuss quantitative synthesis of other colchicine trials
Acknowledged previous COLCOT RCT ($n = 4725$, HR 0.77, 95% CI 0.61 - 0.96)
No incorporating or explaining “differences”
Simply stated CLEAR was a larger trial, with an improved precision

7 meta-analyses have been published in the 3-6 months following CLEAR!

All concluded colchicine is beneficial in post-ACS patients

PubMed: Search: colchicine AND coronary disease Filters: Meta-Analysis, from 2025/1/1 - 2025/7/24

Colchicine Meta-Analyses in 2025

EHJ - IF 36.4

Colchicine for secondary prevention of vascular events: a meta-analysis of trials

Marc-André d'Entremont ^{1,2,3,†}, Michiel H.F. Poorthuis⁴, Aernoud T.L. Fiolet^{5,6}, Pierre Amarenco^{1,7}, Kevin Emery Boczar⁸, Ian Buysschaert⁹, Noel C. Chan ¹⁰, Jan H. Cornel^{6,11,12}, Jalina Jannink¹³, Shirley Jansen¹⁴, Sasko Kedev¹⁵, Anthony C. Keech^{16,17}, Jamie Layland¹⁸, Nathan Mewton¹⁹, Gilles Montalescot²⁰, Domingo A. Pascual-Figal^{21,22}, Alfredo E. Rodriguez²³, Binita Shah^{24,25}, Martin Teraa ²⁶, Aimee van Zelm²⁶, Yongjun Wang²⁷, Arend Mosterd ^{6,13}, Peter Kelly^{28,29}, John Eikelboom^{1,30}, and Sanjit S. Jolly^{1,2,*}; on behalf of the Colchicine Cardiovascular Trialists Collaboration

- In 2^o prevention, colchicine reduced the composite outcome by 12%
- Includes CLEAR authors and published only 3 months after CLEAR trial
- **Apparently frequentist statistics allows investigators to declare both that the treatment does not, and simultaneously does work, all with same evidence base!!!**

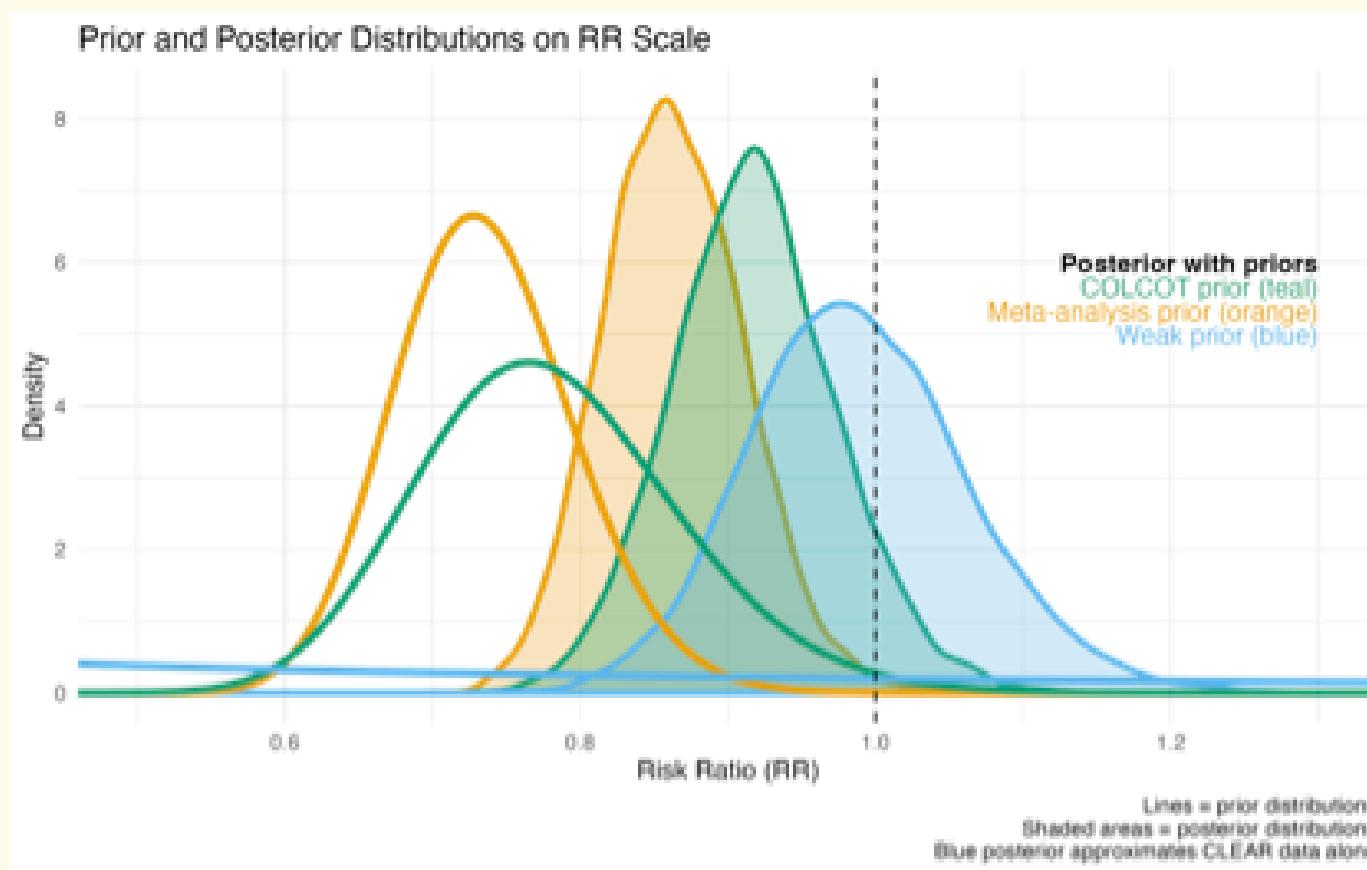

Anatomy of a Bayesian Meta-Analysis

1. Standard difficulties - searching for relevant studies & critical assessment of their quality and appropriateness
2. Additional difficulty - define the priors
3. Specify model (random or fixed effects)
4. Combine likelihood from all studies to compute posterior (via MCMC)
5. Interpret full distribution, not just point estimate

```
1 # brms example for Bayesian meta-analysis
2 library(brms)
3 brm(r | trials(n) ~ 0 + treatment + (1 | Study),
4      family = binomial(),
5      data = nma_data,
6      prior = prior(normal(0, 2), class = b),
7      chains = 4, cores = 4)
```

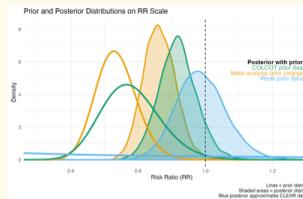

Colchicine Prior Beliefs: Three Perspectives

- Use a community of prior beliefs to assess conclusions' robustness
- **Vague prior:** $N(0, 2)$ → allows CLEAR data to dominate
- **Focused prior:** Based on major pre-CLEAR trial – COLCOT as acknowledged by CLEAR
- **Comprehensive prior:** Based on 2022 meta-analysis (pre-CLEAR)

- Posterior mean RR:
- Vague: 0.99 (95% CrI 0.85–1.14)
- Focused (COLCOT): 0.92 (0.81–1.03)
- Comprehensive (2022 MA): 0.86 (0.78–0.96)

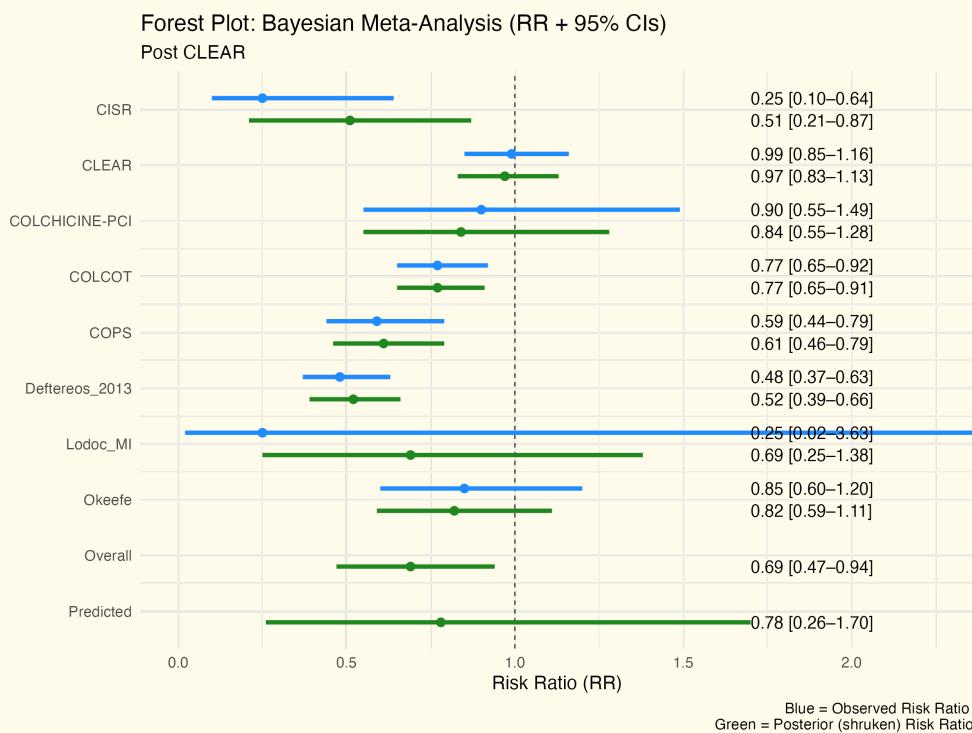

Probabilities for Clinical Thresholds

Prior	$P(RR < 0.8)$	$P(RR < 0.85)$	$P(RR < 0.9)$	$P(RR < 1.0)$	$P(RR < 1.15)$
Weak ($N(0,2)$)	0%	3%	11%	58%	98%
COLCOT-based	1%	11%	38%	92%	100%
Meta-analysis	9%	40%	78%	100%	100%

1. CLEAR & weak prior-> modest 58% probability of some benefit ($RR < 1.0$)
2. COLCOT & meta-analysis priors -> higher probability of some benefit (92-100%) but only modest probability (11-40%) of clinical significance ($RR < 0.85$).
3. **Predictive spread across settings is wide — the next study could differ.**
4. More informed than frequentist 12% reduction with no uncertainty measure

Bayesian forest plot

- Partial pooling with shrinkage of extreme trials
- Bayesian models pull extreme estimates toward the mean
- Particularly helpful in small trials or sparse data
- Hierarchical model accounts for heterogeneity
- Colchicine example - Bayesian next study: RR 0.78, 0.26–1.70 (wider, more realistic than frequentist PI)

What this means for practice today

- CLEAR (RR ~0.99, $p = 0.93$) ≠ proof of no effect; **Absence of evidence ≠ evidence of absence**
- Frequentist meta-analysis conclusion: 12% reduction but no measure of uncertainty
- Bayesian analysis: ~60–100% probability of some benefit $RR < 1$ but only modest (~11–40%) probability of $\geq 15\%$ benefit
- **The evidence does not completely reject the colchicine hypothesis — but does rule out high probability of any very strong benefit**
- **Reasonable:** more evidence, especially if your CID is $\geq 15\%$ relative reduction
- **Reasonable:** targeted use in higher-risk groups + honest discussion of uncertainty

AVR for early asymptomatic patients with severe AS?

- Historically AVR has been restricted to symptomatic patients

“operative treatment is the most common cause of sudden death in asymptomatic patients with AS” - Braunwald, 1990

- More recently, four RCTs & four MAs have all concluded early AVR reduces mortality and morbidity

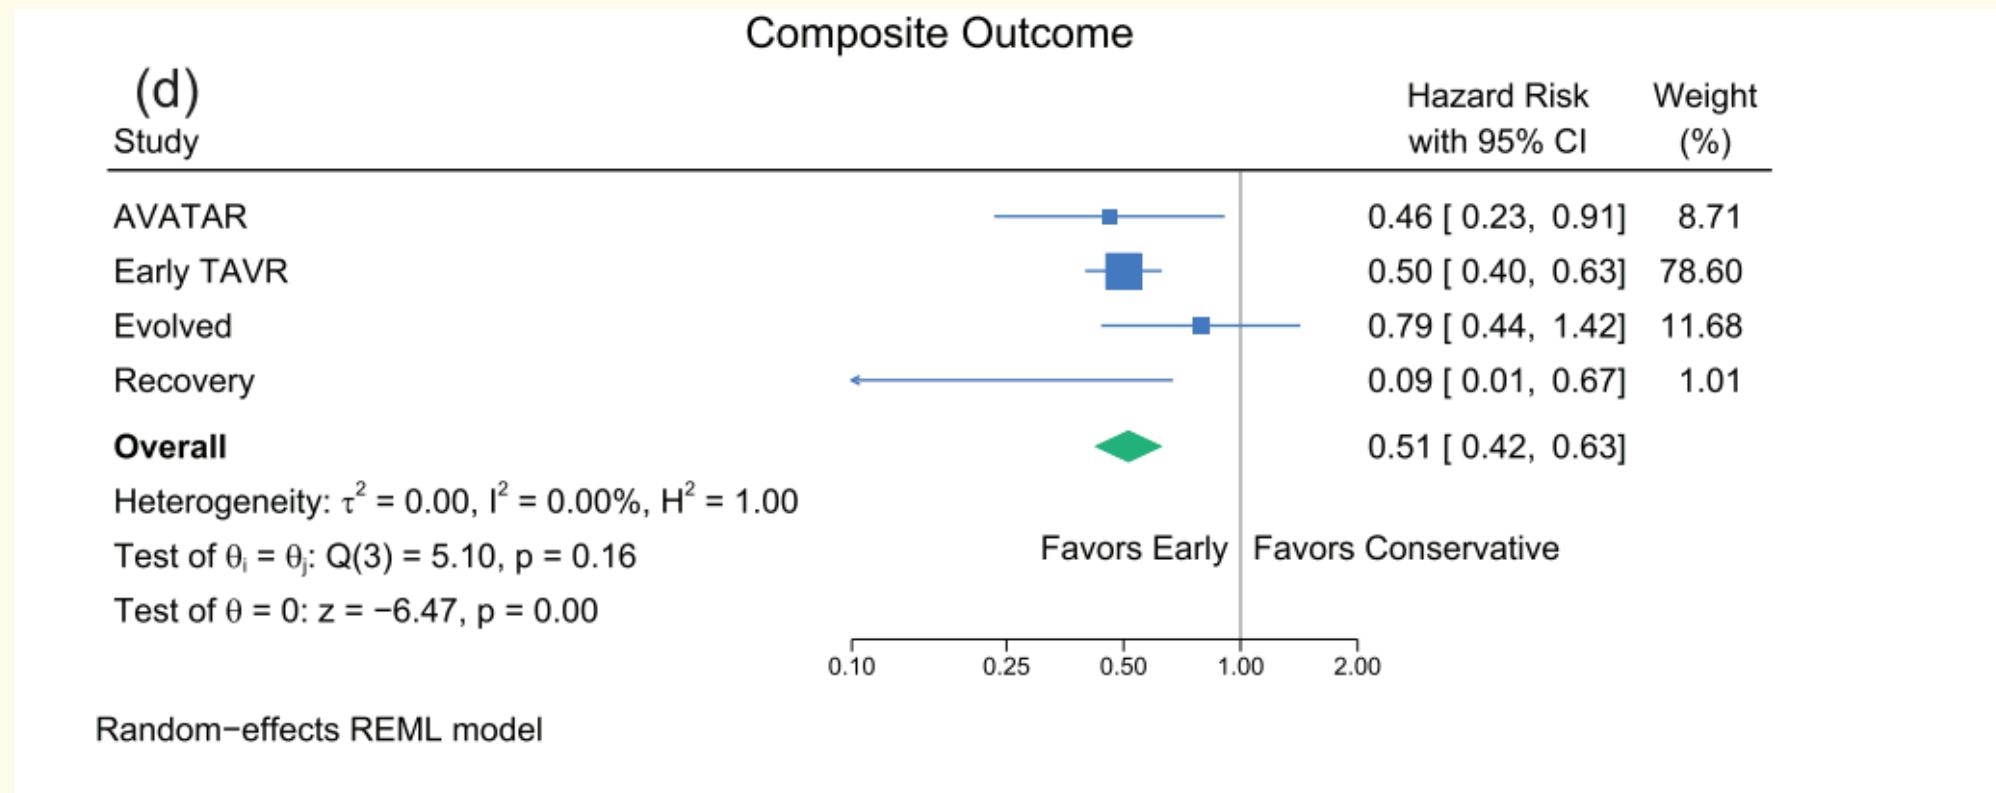

“... the time has come to recommend AVR for asymptomatic patients with severe AS” - Braunwald, 2025

Google scholar: Braunwald E - Citations 436,176; h-index 280

Do we have the temerity to question this opinion & these findings?

Meta-analyses of early AVR in asymptomatic AS

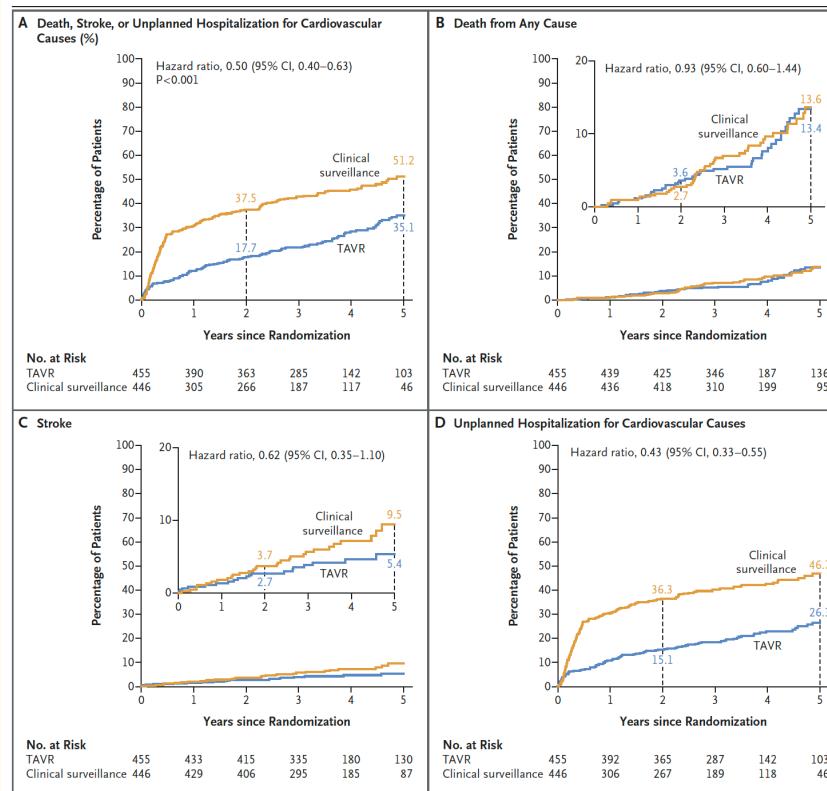

Typical MA -> early AVR reduces mortality and morbidity in asymptomatic AS patients

AJC; Volume 245, 15 June 2025, Pages 11-16

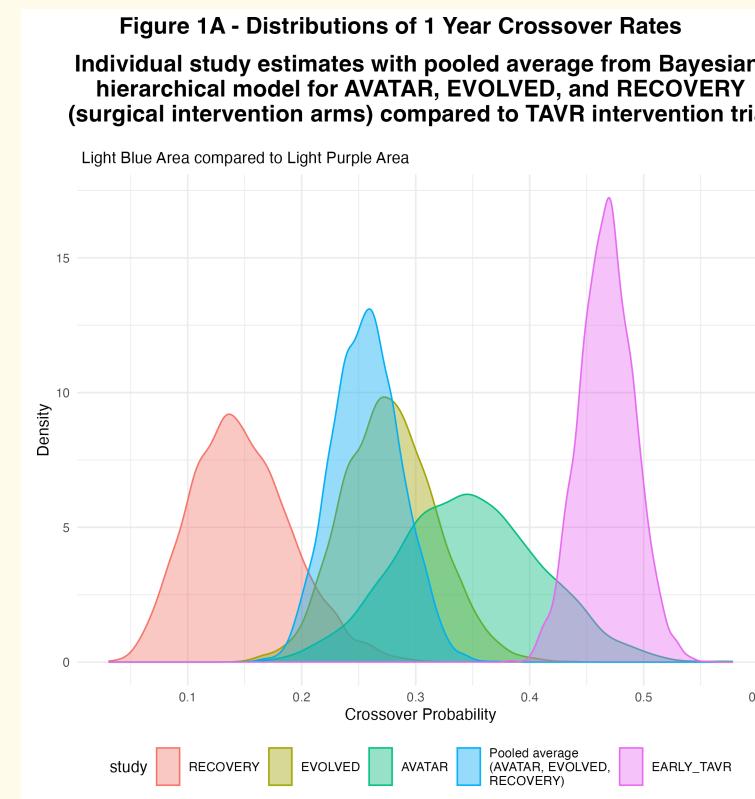

Observations from Early TAVR Trial

1. Meta-analysis results driven by most recent Early TAVR trial
2. Only trial with TAVR for intervention, others used SAVR
3. **No** mortality /stroke benefit
4. **Significant ↑** hospitalizations in CS group 2^o later AVR

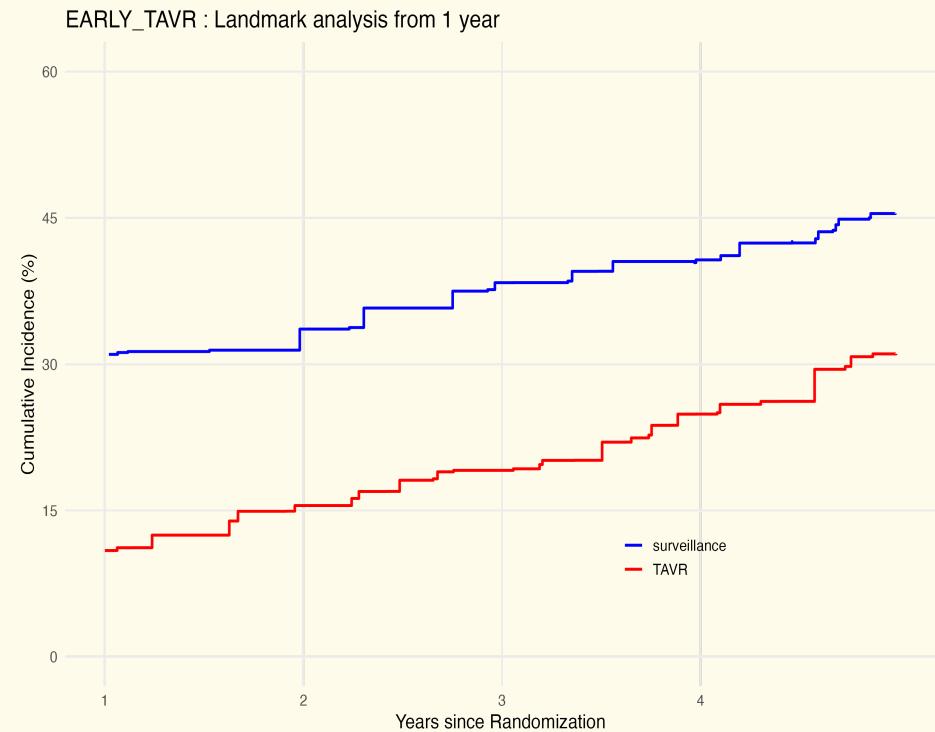

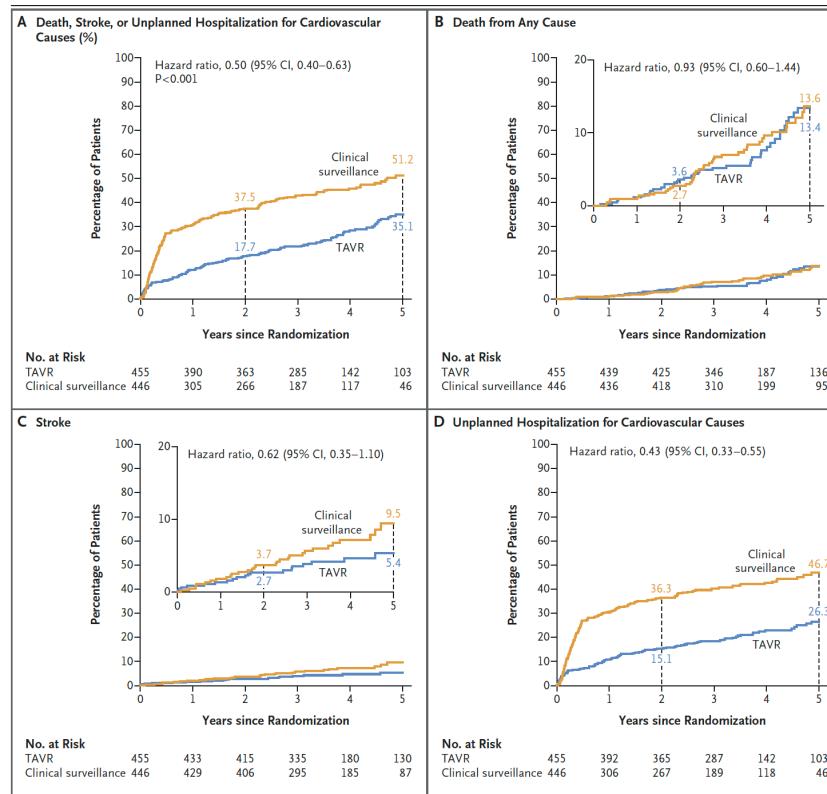

Observations from Early TAVR Trial

5. Xovers $\approx 2X$ other trials, 95% probability of absolute $\Delta > 15\%$!

Observations from Early TAVR Trial

6. Timing of events??? Despite confirmed baseline asx, majority Xovers in first 6 months
7. Landmark analysis of Early TAVR after first year - no difference in any outcomes BTW early TAVR and CS groups

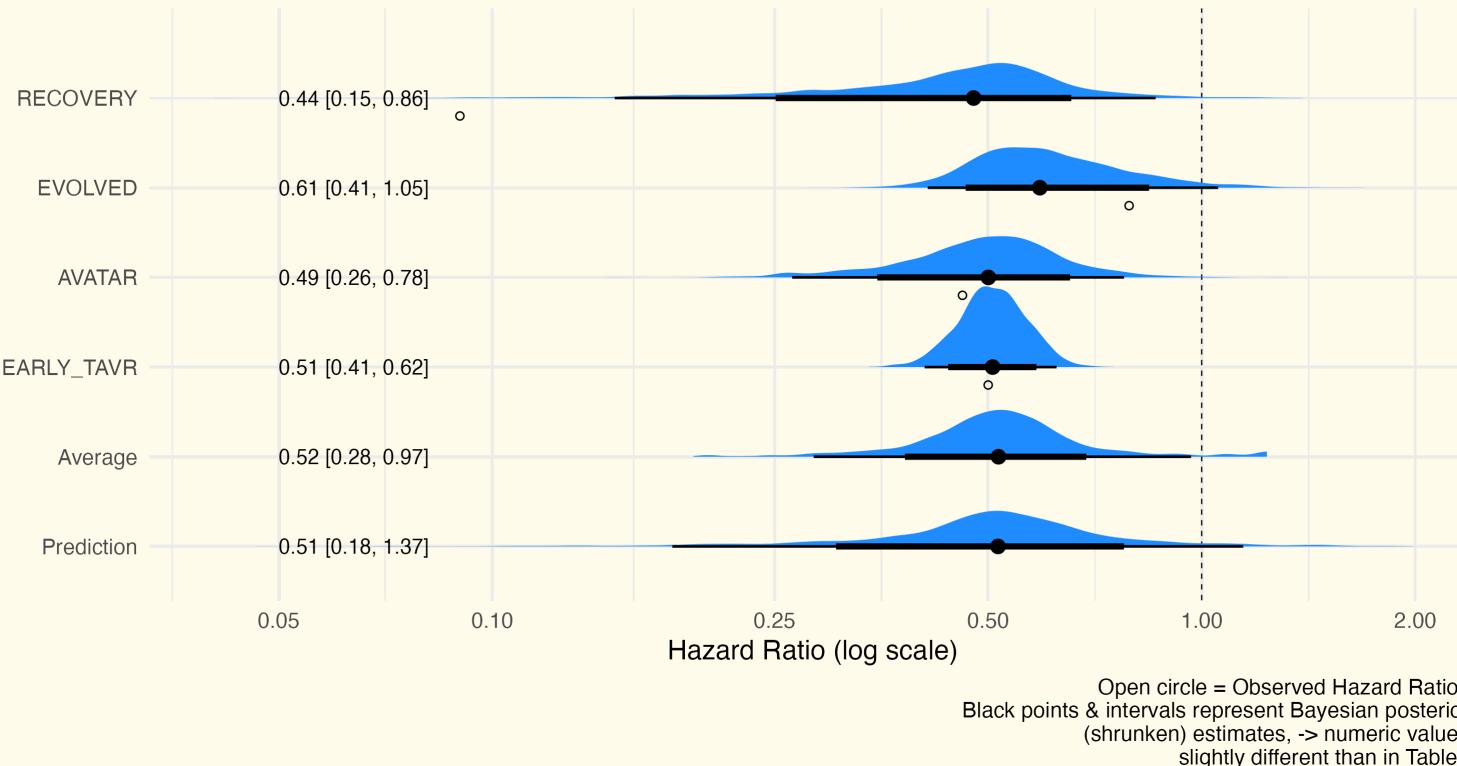

What to expect in the next study (predictive)

Primary outcome: all-cause mortality, stroke or CV hospitalization

Figure 2 - Bayesian Estimates of Primary Outcome from Published Data

Hazard Ratios with 80% and 95% Credible Intervals
(thin and thick lines, respectively)

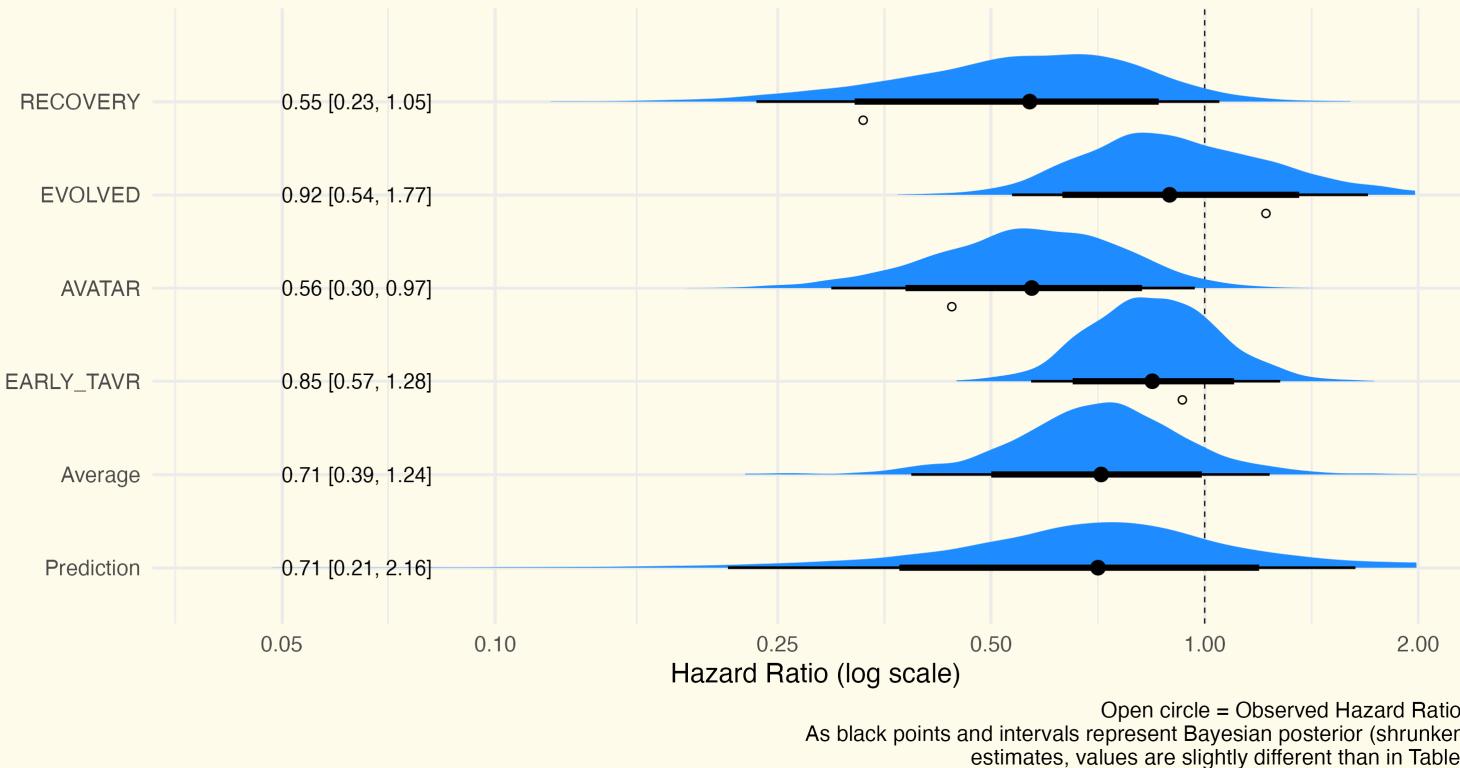

- Frequentist average 0.51 (0.42 - 0.63)
- Bayesian average 0.52 (0.28 - 0.97)
- Bayesian PI (next study) 0.51 (0.18 - 1.37)

What to expect in the next study (predictive)

Primary outcome: all-cause mortality

Figure 4 - Bayesian Estimates of Total Mortality from Published Data

Hazard Ratios with 80% and 95% Credible Intervals
(thin and thick lines, respectively)

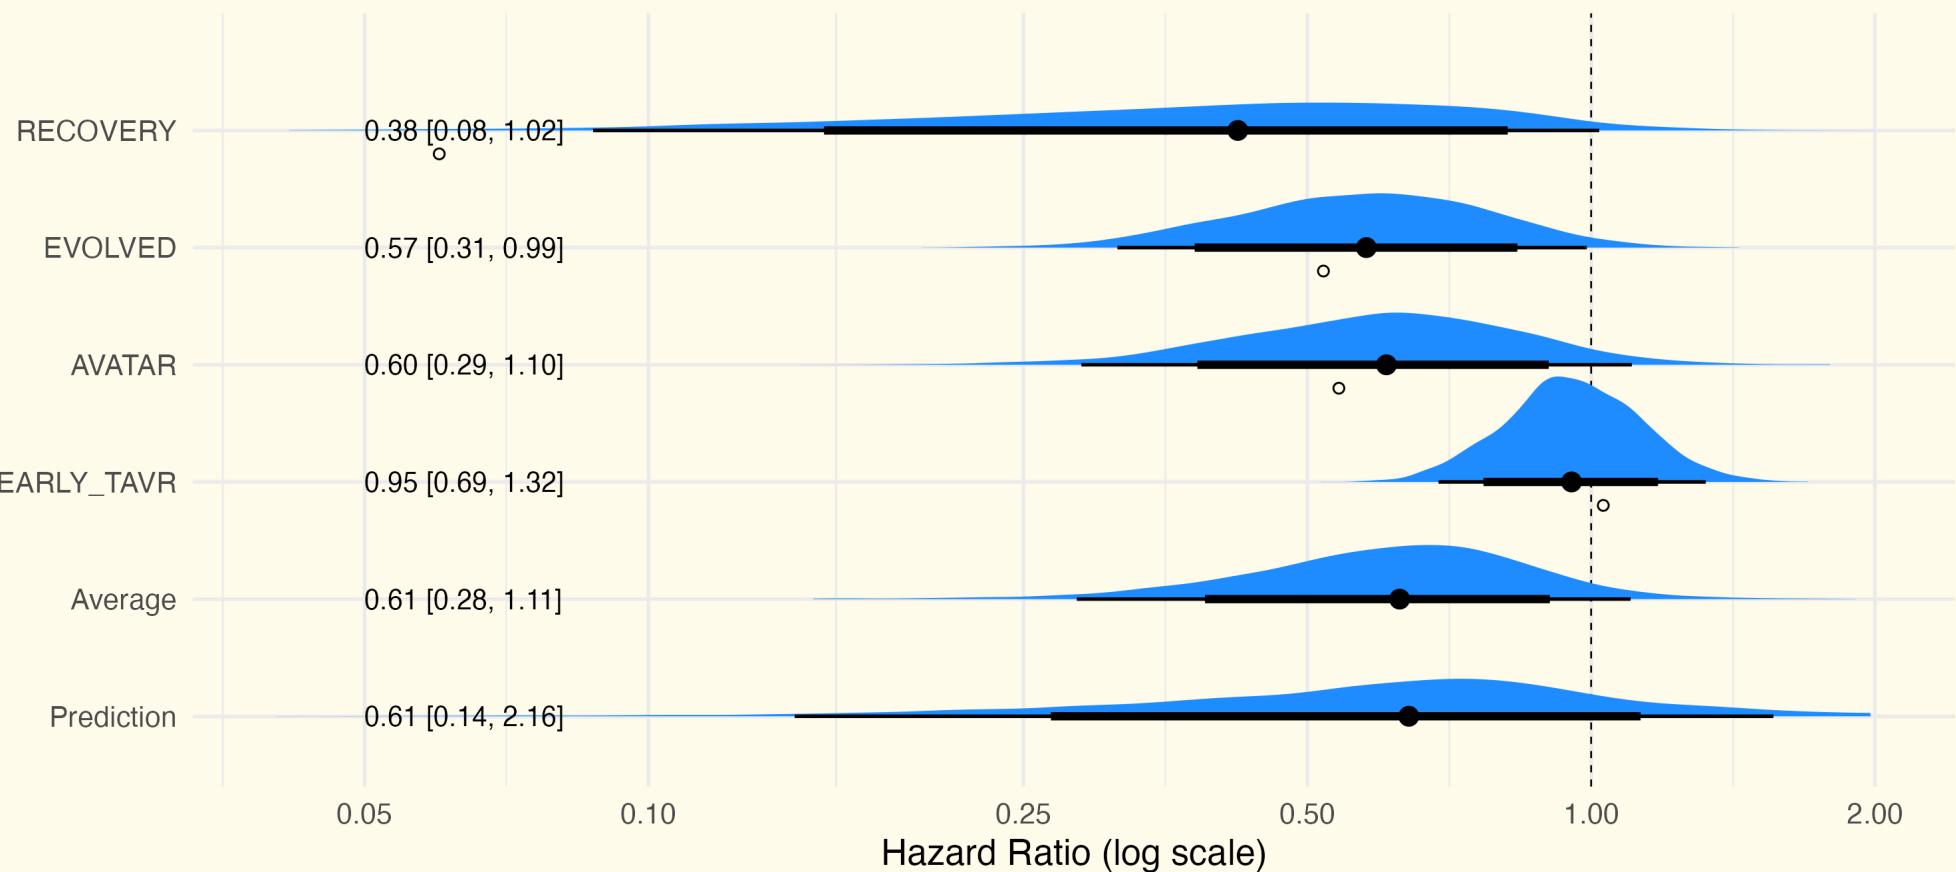

- Frequentist average 0.68 (0.40 - 1.17)
- Bayesian average 0.71 (0.39 - 1.24)
- Bayesian PI (next study) 0.71 (0.21 - 2.16)

Bayesian landmark analyses

Primary outcome: all-cause mortality, stroke or CV hospitalization after 1 year

Figure 3- Bayesian (Posterior) Estimates of Landmark Analysis for Primary Outcome from IPD

Hazard Ratios with 80% and 95% Credible Intervals
(thin and thick lines, respectively)

Open circle = Observed Hazard Ratios
As black points and intervals represent Bayesian posterior (shrunken) estimates, values are slightly different than in Table 2

True benefit vs bias

Meta-analysis driven by Early TAVR events - ↑ CV hospitalization 2^o early crossovers (no mortality Δ, no long term benefit with landmark analysis)

In asx pts with negative baseline exercise testing, which scenario is more likely?

Scenario 1 - benefit of decrease hospitalization occurs immediately following randomization, e.g. in the first year, with no longer term benefits

Scenario 2 - benefit is perhaps small initially but potentially increasing over time.

Logic says Scenario 2 is more likely if TAVR has a true beneficial impact on decreased hospitalizations & death

But landmark analysis compatible with Scenario 1

Existential question: When is an outcome not an outcome?

Answer: When it is an intervention!

True benefit vs bias

Empirical evidence effects from unblinded $\approx \uparrow 30\%$ over blinded trials

1. Untreated subjects knew they had severe disease and untreated -> anxiety and possible conversion to symptomatic status — even in the absence of true progression of cardiac symptoms. treated.
2. Researchers are likely TAVR “believers” knew who was untreated -> increasing probability of attributing any symptoms, whether of cardiac or not, to the underlying AS
3. Early treatment group knew they were “fixed” and less likely to consult for any symptoms, again whether cardiac or not.
4. Researchers knowing these patients had been treated might also be less inclined to attribute any symptoms to the cardiac condition

All scenarios $\rightarrow \uparrow$ differential hospitalizations btw early treatment and CS & suggests spurious, rather than true, early TAVR benefit.

Don't generalize early TAVR as standard of care; prioritize shared decision-making and further robust evidence.

Take-Home Messages

- Meta-analysis is powerful, but not infallible
- Bayesian meta-analysis offers:
 - ↑ flexibility
 - ↑ transparency
 - ↑ acknowledgement & understanding of uncertainty
 - makes model assumptions explicit
 - respects the full evidence stream
 - avoids availability bias, dichotomous thinking
 - Provides direct answers to questions like:
 - *What's the probability RR < clinical meaningful effect?*
 - *What's the probability absolute benefit > clinical meaningful effect?*
 - enhanced statistical reasoning -> ↑ meta-cognition & ↑ clinical wisdom

Thank You

Let's keep thinking critically
